   Limiting Distribution A MC has a limiting distribution \underline{q} if for any initial distribution \underline{P}(0)
 \underline{P}(\infty) \equiv \lim_{n \to \infty} \underline{P}(n) = \underline{q} \text{ or } \underline{P}(0)P^{\infty} \equiv \underline{P}(0)\lim_{n \to \infty} P^{n} = \underline{q}
    Theorem: A MC has a limiting distribution \underline{q} iff
 q_i = \lim_{n \to \infty} P_{ij}^{(n)} \, \forall i, j
*i.e. every row of P^{\infty} equals \underline{q} (row vector)

Steady State (Stationary) Distribution \underline{\pi} is a steady state distribution of a MC if \underline{\pi} = \underline{\pi}P
   Theorem: If a limiting dist. exists \underline{q}=\underline{P}(\infty), then it is also
    a steady state dist.

Ergodic: For a finite-state, irreducible, and aperiodic MC,
 then (1) Limiting dist. \underline{q} = \lim_{n \to \infty} \underline{P}(n) exists and q_j = \lim_{n \to \infty} P_{ij}^{(n)} \ \forall i, j (2) Steady state dist. \underline{\pi} is unique.
    (3) \underline{\pi} = \underline{q}
(a) \underline{\pi} = \underline{q}
How Fast Does \underline{P}(n) Converge to \underline{\pi}? (1) \underline{\pi}^T = \underline{\pi}^T P^T
*\underline{\pi}^T is an eigenvector of P^T w/ eigenvalue 1
(2) Suppose P^T has eigenvectors U \equiv [\underline{\pi}^T, \underline{u}_2, \dots, \underline{u}_D] and eigenvalues \Lambda \equiv \operatorname{diag}[1, \lambda_2, \dots, \lambda_D], then
P^T U = U \Lambda \Longrightarrow P^T = U \Lambda U^{-1} = 0
Therefore, \Lambda^n = (U \Lambda U^{-1})^n = U \Lambda^n U^{-1}
Therefore, \Lambda^n = \operatorname{diag}[1, \lambda_2^n, \dots, \lambda_D^n]
(3) For gradiar M \subset P^n \to [\underline{u}_1, \underline{u}_2, \underline{u}_1]^T is a rank 1)
 (3) For ergodic MC, P^n \to [\underline{\pi}, \dots, \underline{\Lambda}D] (i.e. rank 1) Therefore, \# of non-zero eigenvalues is 1, so the rest of the eigenvalues must be |\lambda_i| < 1 \,\forall i \geq 2 \,\text{s.t.} \,\Lambda^n = \text{diag}[1, 0, \dots, 0] Rate of Convergence: Depends on the 2nd largest eigenvalue [\underline{\pi}D^T] = (\underline{\Lambda}D^T)
   Rate of Convergence: Depends on the 2nd largest eigenvalue of P^T i.e. (\lambda_2)^n is the rate of convergence. Bayesian Network (DAG): Network of RVs X_1, \ldots, X_n w/directed edges *Not State-Transition Diagram: 1 RV w/different values
   *Not State-Transition Diagram: I RV w/ different values w/ different probabilities to each value.

*Fully Connected Graph (General): No special dependency structure, so doesn't give additional info as we can write joint dist. from defn. (true for any graph).

*Non-Fully Connected Graph (Bayes' Net): Conveys useful
   Factorization of Joint Dist. Suppose the dependencies among RVs can be represented by a DAG, then
    From the represented by a Bird, then
P(x_1, ..., x_n) = \prod_{i=1}^{N} P(x_i \mid \text{pa}\{X_i\})
*General: P(x) = \prod_{i=1}^{N} P(x_i \mid x_{i-1}, x_{i-2}, ...)
    P(x_1 \mid x_0) = P(x_1)
Topological Ordering: Often index the RVs s.t. each child
Topological Ordering: Often index the RVs s.t. each child has an index greater than those of the parents. Fact: Every DAG has at least one topological ordering. Conditional Independence: A \perp B \mid C if (1) P(a, b \mid c) = P(a \mid c) P(b \mid c) \forall a, b, c (i.e. A and B are indep. given C) (2) P(a \mid b, c) = P(a \mid c) \forall a, b, c (i.e. B gives no add. info about A given C) (Common Cause (T-T): A \perp B \mid C, o.w. A \not\perp B (Common Effect (H-H): A \perp B, c, w. A \not\perp B (Common Effect (H-H): A \perp B, c, w. A \not\perp B) (Common Effect (H-H): A \perp B, c, w. A \not\perp B) (Common Effect (H-H): A \perp B, c, w. A \not\perp B) (Common Effect (H-H): A \perp B \mid C) (Common Effect (H-H):
   and B are d-separated by C, i.e. A \perp B \mid C
Blocked Path: An undirected path is blocked if it includes a

```

```
2. The node is head-to-head, but neither itself nor any of its descendants are in set \mathcal C (Case 3) Markov Boundary (Blanket): Minimal set of RVs \mathcal M that
isolate X_i from all the remaining RVs, i.e. X_i \perp \mathcal{N} \setminus (\{X_i\} \cup \mathcal{M}) \mid \mathcal{M} \times \mathcal{N}: Set of all RVs \mathcal{M} = \mathcal{M} = \mathcal{M} \times \mathcal{M}. Set of all RVs \mathcal{M} = \mathcal{M} = \mathcal{M} \times \mathcal{M}.
*\mathcal{M}= parents \cup children \cup co-parents: Blocks all paths b/w X_i and the remaining nodes.

Markov Random Field: Represent RVs as an undirected graph s.t. conditional independence \mathcal{A}\perp\mathcal{B}\mid\mathcal{C} hold iff all paths b/w \mathcal{A} and \mathcal{B} so through \mathcal{C}.

*Markov blanket of X_i: = set of neighbours of X_i: No Order: Simplifies, but no way to order the RVs, so lose directivity, lose info.

Independence: See if all paths b/w \mathcal{A} and \mathcal{B} are blocked by \mathcal{C} (i.e. given \mathcal{C}).
 (i.e. given C)

Clique: A set of nodes s.t. there is link b/w any pair of them

Maximal Clique: A clique s.t. we cannot add another node in
  the set and maintain a clique.
Hammersley-Clifford Theorem: Let \underline{x}_{\mathcal{C}} denote the values of RVs in set C. Any strictly postiive dist. P(\underline{x}) that satisfies a Markov random field can be factorized as P(\underline{x}) = \frac{1}{Z} \prod_{c \in C} \psi_c(\underline{x}_c) \stackrel{e.g.}{\longrightarrow} \frac{1}{Z} e^{-\sum_{c} E(\underline{x}_c)}
*Z = \sum_{\underline{x}} \prod_{c \in C} \psi_c(\underline{x}_c): Normalization constant *\Pi_{c \in C}: Product of all maximal cliques
  *\psi_c(\underline{x}_c) \stackrel{e.g.}{=} e^{-E(\underline{x}_c)}: Potential function over the clique c
*\psi_{\mathcal{C}}(\underline{x}_{\mathcal{C}}) \cong e^{-D(\underline{x}_{\mathcal{C}})}: Potential function over the clique c (not necessarily a prob.)
*E(\underline{x}_{\mathcal{C}}): Energy function over the clique c
Moralization or Marrying the Parents (BN to MRF) Always possible, but some dependency structure will be lost 1. Add edges b/w all pairs of parents of the same child 2. Remove all directed edges (i.e. make it undirected)
Hidden Markov Model (HMM):
*State-transition Prob.
"State-transition Prob. P[Z_n = z_n \mid Z_{n-1} \equiv z_{n-1}], \ Z \leq n \leq N *Initial State Dist. P(z_1) \equiv P[Z_1 = z_1]
 *Note: Can be continuous (density).
Notes: (1) Z_n nodes are H-T or T-T and Z_1,\ldots,Z_N are unobserved \Longrightarrow No indep. among X_n's, also \{X_n\} are not a MC. (2) Latent var. Z_1,\ldots,Z_N are MC \Longrightarrow Z_{n+1}\perp Z_{n-1}\mid Z_n \Longrightarrow e.g. \{X_1,X_2\}\perp\{X_3,\ldots,X_N\}\mid \{Z_3\} Common Problems
1. Given HMM, find P(\underline{x}) for any \underline{x}=\{x_1,\ldots,x_N\}
2. Given HMM/\underline{x}, find most likely z_n
3. Given HMM/\underline{x}, find most likely seq. of states \underline{z}=\{z_1,\ldots,z_N\} Message Passing Algos: Given HMM, find P(\underline{x}) \forall \underline{x}
 \alpha(z_n) \equiv P[\underbrace{X_1 = x_1, \dots, X_n = x_n}_{}, \underbrace{Z_n = z_n}_{}], \ 1 \le n \le N
